

Model S wh/mile Data from the TMC Lifetime wh/m thread

April 22, 2014

1 Lifetime Average wh/mi Data

The data below is self reported data from Model S drivers on the TMC website in the thread started by GeekGirl in January 2013.

1.1 Data Summary

	Drivers	Miles	Locales	wtdAvg(wh/m)	Avg(wh/m)	Median(wh/m)	Stdev(wh/m)
All	193	2620826	36	332	336	336	34
Clean	154	2467026	36	330	330	332	30

Table 1: Number of drivers, locales, and several estimates for the center of the wh/m distribution. In the second row, I use exclude very short driving histories because their wh/m numbers are often not indicative of long term energy use. This eliminates about twenty percent of the drivers, but less than five percent of the miles driven. I use the clean data set below.

In addition to the average and median wh/m, I include a mile weighted average, wtAvg, which is just the total energy (sum drivers wh/m * miles) divided by the total miles driven. All three estimates for the center of the distribution are very close, so it doesn't make much difference which one we use. I will mostly use the wtAvg below.

1.2 Expectations

- Wheels. The range calculator on the Tesla website shows 21" wheels increasing energy consumption by 6% on an 85kwh battery.
- Battery. The same calculator shows the 60kwh battery uses about 10% less energy than the 85kwh battery. (It is not clear to me what accounts for this difference; the small difference in weight doesn't seem large enough to account for it.)
- Temperature. We expect a fairly strong negative correlation between wh/m and the severity of winter.

1.3 References

For a good quantitative discussion of the factors that affect energy use, see ChadS's post here. For a nice plot showing the strong temperature dependence of wh/m on temperature, see this graph. Cliff Hannel has an EVTripPlaner which also estimates these factors.

1.4 Winter

A large fraction of the data set is up to date through March of 2014, just after winter. So I expect the averages are a bit high. If we do these calculations again at the end of September we should see somewhat lower numbers (this would be a good time to update numbers). I don't think the effect will be dramatic for two reasons. First, as we will see later, for drivers who live in areas with mild winters (the South, the Southwest, California), winter has a relatively small effect on mileage. Second, we have quite a few miles recorded now, so it will take a lot to move the needle. In any event, the average of the end of winter and end of summer numbers should be close to the year round average.

1.5 More Detailed Summary

Here is a slightly more detailed summary:

	Wh	Miles	State	MBattery	Wheels	JanTemp
1	Min. :256.0	Min. : 2193	CA :42	40 : 3	19 :93	Min. : 1.00
2	1st Qu.:309.0	1st Qu.: 9751	TX :12	60 :33	21 :35	1st Qu.:26.00
3	Median :332.0	Median :15222	FL :10	85 :47	M :17	Median :42.00
4	Mean :330.2	Mean :16020	IL :10	P85 :46	NA's: 9	Mean :36.87
5	3rd Qu.:351.0	3rd Qu.:20915	AZ : 9	S85 :21		3rd Qu.:45.00
6	Max. :406.0	Max. :47142	OR : 7	NA's: 4		Max. :67.00
7			(Other):64			

Table 2: Summary of the Data

1.6 Histogram

Below is a histogram of the clean data set.

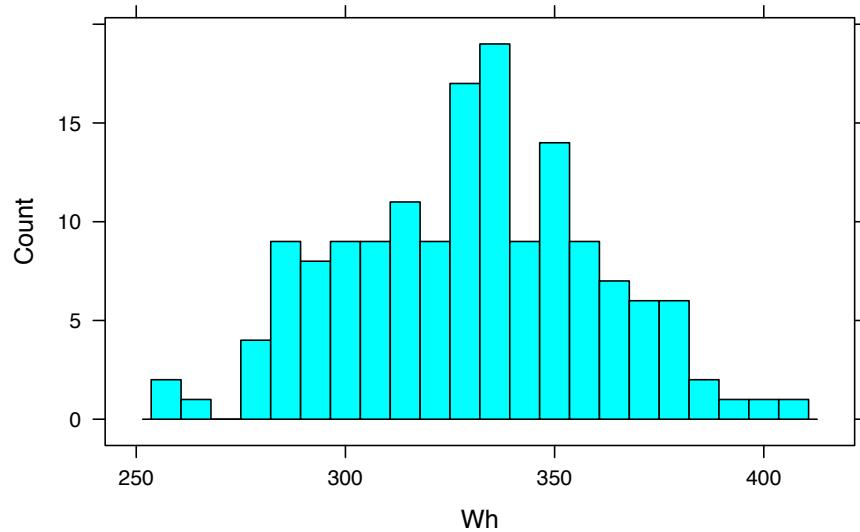

Figure 1: Histogram of Wh/mile data.

araxara	293	27876	AZ	85	M	04/04/14	42	P85

There are three outliers on the left tail of the distribution at around 260 (jerry33, Sparrow, svoelpel). All drive 19" wheels and live in states with mild winters, but even still, the numbers are clearly exceptional. Somewhat surprisingly, all of these drivers have 85s (P85 for Sparrow). Given that the 60s are more efficient, I would have expected to see some 60s having the lowest numbers. Perhaps if we collect more data on the 60s that will happen; currently the majority of our data is 85s. gnelson is also somewhat of an outlier as he gets a very good wh/m average despite driving with 21" wheels.

jerry33 and Sparrow's monthly numbers are even more impressive as they are sometimes less than 250. See the plots in the monthly data section below.

1.8 Upper Bound

	Wh	Miles	State	Battery	Wheels	LastUpdate	JanTemp	MBattery
neroden	406	9493	NY	85	19	04/07/14	21	85

Rodolfo Paiz	370	3500	FL	85	<NA>	10/28/13	58	P85
smd	369	7950	CA	85	<NA>	05/13/13	45	85
yobigd20	368	44049	NJ	85	19	04/09/14	31	P85
FlasherZ	366	22507	IL	85	M	04/03/14	25	S85
drbradfo	364	16363	OR	85	M	04/04/14	33	85
stsanford	364	16500	NY	<NA>	<NA>	04/04/14	21	<NA>

The highest upper bound is from neroden at 406. Neroden lives in Ithaca so (I assume) has to deal with bad winters and with lots of hills. The next largest numbers are both from WA: EarlyAdopter at 399 and brianman at 394. In general WA and OR numbers are higher than one might expect just based on temperature, as others have noted. Presumably this has to do with having lots of hills and many days with wet roads, but with the limited data we have on this thread it's impossible to pin down the exact causes.

1.9 Geographical Distribution of Data

Table 3: Wh/mile aggregated by locale.

1.10 Colored Map

Unfortunately, I couldn't figure out how to include Alaska (deepest blue at 384), Hawaii (lightest blue at 307), Quebec (mid blue, 331), Ontario (dark blue, 362), Alberta (mid blue, 332) or British Columbia (mid blue at 334).

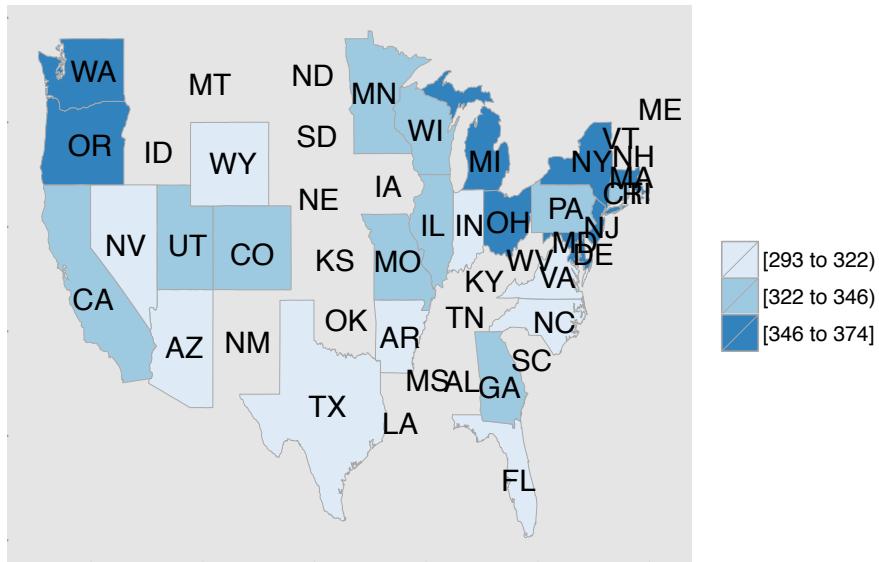

Figure 2: Map of wtAvg wh/m data.

1.11 Distribution of Battery and Wheels Sizes

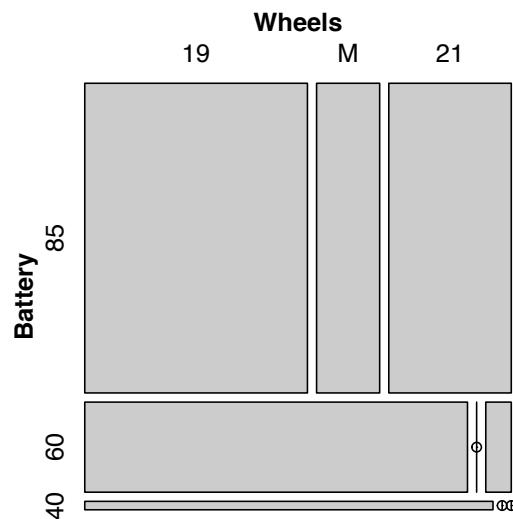

Figure 3: Proportion of cars by battery and wheel type in the clean data set.

1.12 Average wh/m by Battery and Wheels Sizes

	Battery	Wheels	wtdAvg	Avg	Median	Miles	Drivers	AvgJanTemp
1	40	19	313	321	307	34793	3	26
2	60	19	309	310	312	502646	30	35
3	85	19	330	329	334	956348	60	36
4	60	21	290	292	292	12840	2	62
5	85	21	343	342	342	509832	33	41
6	85	M	343	343	346	342945	17	32

Table 4: Wh/mile aggregated by Wheel and Battery. 'M' means a mixture of 19s and 21s

Below is a box and whiskers plot of the same data giving a better picture of the distribution.

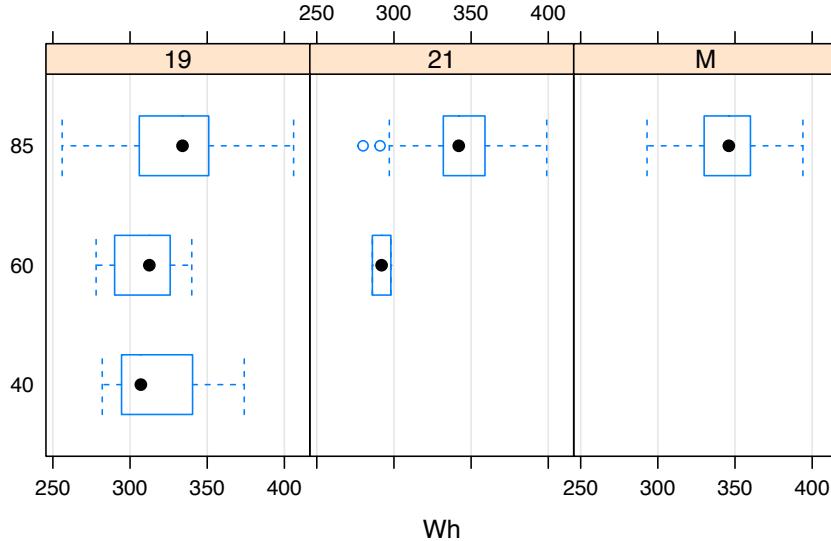

Figure 4: Box and Whiskers plot of Battery vs Wh grouped by Wheel. The black dot is the median and the box is the 25th-75th interquantile range.

In the table we see the average January temperature of the locations for the 60/19 and 85/19 are about the same, so if the 21wh/m difference between these 85 and 60kwh batteries should not be affected by climate differences in the locations of these two groups of cars.

The situation is a bit less clear when comparing Wheels. From the table, average January temperature of the locations of 85/21 combinations is slightly higher than the 85/19 combination. Because higher temperatures are associated with lower wh/m, the 13wh/m wtAvg difference between the 85/21s and 85/19s may underestimate of the real difference between 21 and 19 inch wheels. The linear model we fit below gives a slightly larger difference of 16wh/m.

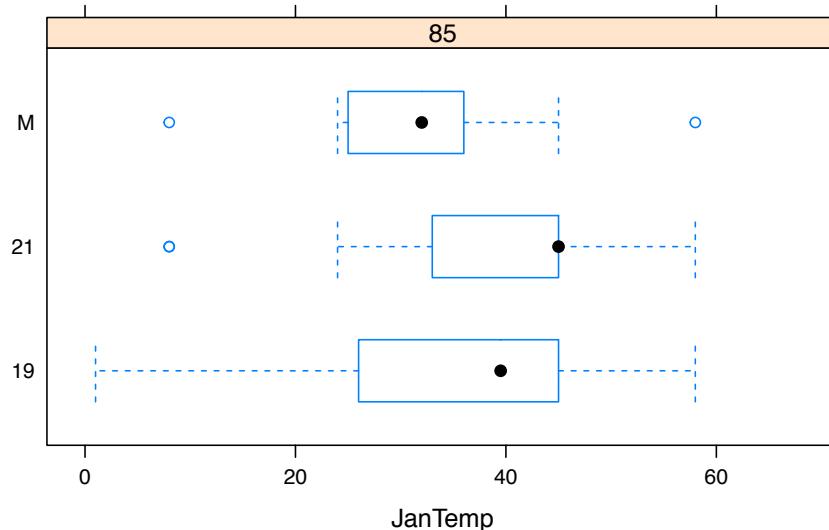

Figure 5: wh/m for the 85kwh battery vs average January temperature, grouped by Wheel. The black dots are the median of the distribution.

1.13 wh/m vs JanTemp conditioned on Wheel and Battery Sizes

The left panel shows that for all average January temperatures of the locations of the cars, the 60s tend to have lower wh/m numbers than the 85s. The strong negative correlation with temperature is also clear on this plot.

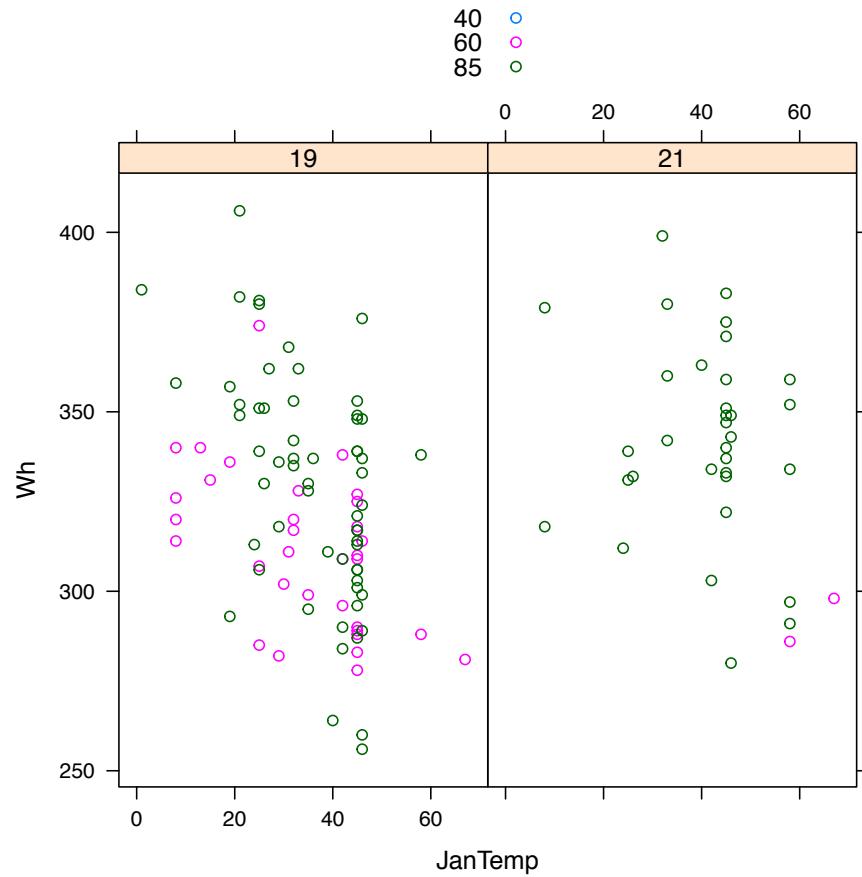

Figure 6: We drop the mixed Wheel combinations in this plot.

1.14 Simple Model

This section is just for fun. I don't put a lot of weight on the exact numbers that come out, but the trend and magnitudes seem about right.

We can try to fit a simple model to the data to predict wh/m given what we know. The model has to be simple because the data set is small. We don't know a lot of the relevant factors that affect a given driver's wh/m (e.g. driving style, typical elevation changes, typical road conditions where he or she lives) so we don't expect the model to be terribly accurate. At the same time, there are clear geographical and wheel/battery patterns in the data so we should be able to say something.

The main difference between the states and provinces as far as annual energy consumption goes is the severity of the winter. One simple way to characterize the severity of winter is by the average temperature in January. I used the 30 year average of the average January temperature from the NWS because it was easy to find. The main purpose of using this variable as a proxy for location is that it has the right quantitative characteristics. The absolute scale doesn't matter, as long as all states are shifted by similar amounts. However as this winter was severe in the east and mild in the west, we would likely get better results if we used this year's average January temperatures (heating degree days would be another option).

In any case, the model is simply a linear model in average JanTemp, Wheel Size, and Battery size. To fit the model, I drop "mixed" wheel data and set 40 kwh batteries to 60 (they should be the same).

The regression coefficients are:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	341.9711	7.7096	44.36	0.0000
JanTemp	-0.9158	0.1794	-5.10	0.0000
Wheels21	16.4614	5.5300	2.98	0.0035
Battery85	20.4723	5.3971	3.79	0.0002

Table 5: Linear Model

and the adjusted R^2 is .27.

In words, the model predicts your annual wh/m will be 342 minus .9 times the average January temperature of your state (in degrees F, included in the Locale data table above) plus 20 if you have an 85 battery, plus another 16 if you have 21 inch wheels. If you have 21 inch wheels half the time, and 19 inch the other half, you should add 8 instead of 16 etc.

I include the predictions of the model for all drivers at the end, assuming in the case of mixed wheels that it is half 19 and half 21.

1.15 Plot of Predicted vs Actual Wh/m

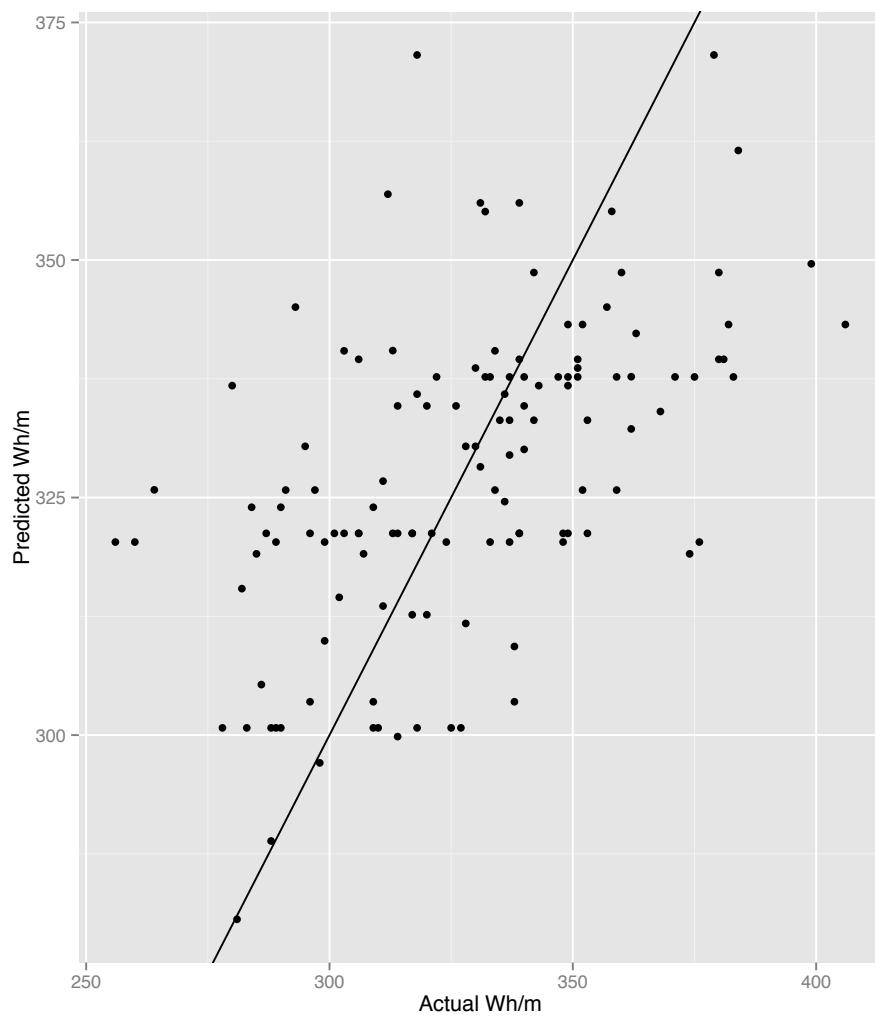

Figure 7: Predicted vs Actual Wh/m

1.16 Monthly Data

I plot time series data below for each driver for whom I have at least five updates. Note that the points in the graph are "monthly" wh/m numbers, not cumulative ones. For some drivers, the updates are not regularly spaced, so a given point corresponds to the wh/m since the previous point (e.g. the previous two months if the previous update was two months prior). Also, for a couple of drivers, there are two plots - one showing monthly numbers they provided and one derived from

their cumulative numbers.

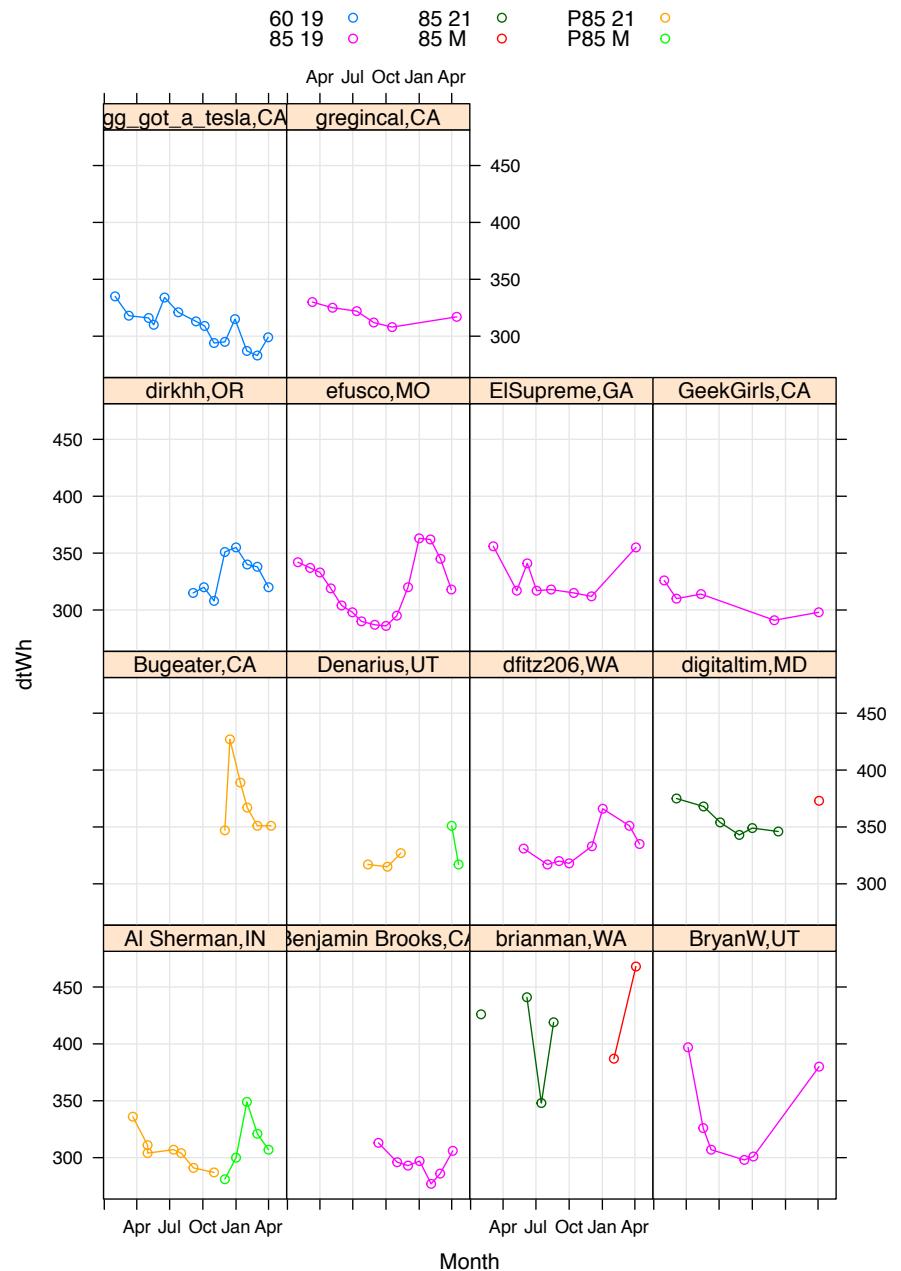

Figure 9: Selected time series
